A digital image is a two-dimensional array of picture elements, or pixels, each representing a color or intensity value. This array serves as the fundamental unit for processing tasks. Gonzalez emphasizes that digital images can be represented in various forms, including:

- Binary Images: Pixels are either black or white.
- Grayscale Images: Pixels have intensity levels, typically ranging from 0 (black) to 255 (white).
- Color Images: Pixels contain multiple components, such as RGB (Red, Green, Blue), to represent a full spectrum of colors.

Recognizing these representations is essential for selecting appropriate processing techniques.

Image Acquisition and Sampling

The process begins with acquiring an image through sensors or scanners, which convert real-world scenes into digital data. Gonzalez discusses the critical aspects of sampling and quantization:

- Sampling: The process of converting continuous signals into discrete samples.
- Quantization: Mapping the sampled values into a finite set of levels.

The resolution and quality of a digital image depend heavily on these stages, impacting subsequent processing and analysis.

Image Enhancement and Restoration

Once an image is digitized, the next step is often improving its visual quality or restoring it from degradation. Gonzalez categorizes these processes as:

- Image Enhancement: Improves visual appearance or emphasizes certain features.
- Techniques include contrast stretching, histogram equalization, and filtering.
- Image Restoration: Aims to reconstruct or recover an image degraded by factors like blur or noise.
- Techniques involve inverse filtering, Wiener filtering, and deconvolution.

These foundational methods are critical in preparing images for further analysis or interpretation.

Fundamental Techniques and Algorithms in Image Processing
